

Majd's Platform

Project overview

I built the platform from your specification. It's a reusable base for business applications, so that when we start a new project we don't have to rebuild sign-in, permissions, admin screens and reports from scratch.

It has two parts: a .NET API for the backend and an Angular website for the interface. I'll show you the website.

Sign-in and permissions

I sign in as an administrator. Every screen and every action is protected by permissions. I can create a role, choose exactly what it may do, and give it to a user. That user then sees only what the role allows, and it takes effect immediately. I can also grant or deny a single permission to one person on top of their roles.

Audit

Everything people do is recorded: who did it, what changed, and whether it succeeded. Refused attempts are recorded too, for example someone without a token trying to reach the system.

Dashboard

These tiles load their own data, and each user can hide or reorder them for themselves.

Two languages

I switch to Arabic and the whole page flips to right to left, live, including the menu and the dashboard text. It remembers the choice, and each user can have their own language.

Import and export

I can export the user list to Excel, CSV or PDF, and large exports run in the background and notify me when they are ready. I can also import users from a file, with a report of which rows failed and why.

Plugins

This is the part I'd like to highlight. A plugin is a package that adds a whole feature without changing the platform's code. This Tasks plugin brings its own screens, permissions, menu entries, settings and Arabic translations. If I turn it off, its menu and permissions disappear. If

I turn it on, they come back. Upgrades can be rolled back, and packages can be signed so only trusted publishers can install them.

Behind the scenes

It has background jobs with retries, email notifications, file storage with a recycle period, health checks, API documentation, caching, and logging. There are 428 automated tests on the backend, 127 on the frontend, and 49 browser tests that click through the real site, including accessibility checks.

Where it stands

Every requirement in the document has an implementation. Of the 201 functional requirements, I count 146 as fully complete and 55 as partially complete, and none are missing. I keep that in a traceability file in the repository, so you can see which is which. What remains is depth, not missing features: plugins can't yet ship their own database tables or apply changes without a restart, there are no SMS or push notifications because that needs a provider account, and I haven't yet run it against a live Redis server or measured performance.

So it is a solid base to build the next application on, and I'd like to finish those remaining items next.
